## 1 Introduction

Given the opportunity to review the design document and related smart contract source code of the Aptos support in the cBridge protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

### 1.1 About cBridge Aptos

Celer cBridge introduces the cross-chain token bridging experience with deep liquidity for users, highly efficient and easy-to-use liquidity management for both cBridge node operators and liquidity providers who do not want to operate cBridge nodes, and developer-oriented features such as general message bridging for cases like cross-chain DEXs and NFTS. The audited cBridge Aptos is the extension of cBridge in the Aptos blockchain, and currently supports a canonical token bridge model. The basic information of audited contracts is as follows:

#### 1.2 About PeckShield

PeckShield Inc. [10] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

High Medium High Impact Medium High Medium Low Medium Low Low Low High Medium Low Likelihood

Table 1.2: Vulnerability Severity Classification

## 1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [9]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild:
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact, and can be accordingly classified into four categories, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

Table 1.3: The Full List of Check Items

Category	Check Item
	Constructor Mismatch
	Ownership Takeover
	Redundant Fallback Function
	Overflows & Underflows
	Reentrancy

	Holistic Risk Management
	Avoiding Use of Variadic Byte Array
	Using Fixed Compiler Version
Additional Recommendations	Making Visibility Level Explicit
	Making Type Inference Explicit
	Adhering To Function Declaration Strictly
	Following Other Best Practices

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [8], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings. Moreover, in case there is an issue that may affect an active protocol that has been deployed, the public version of this report may omit such issue, but will be amended with full details right after the affected protocol is upgraded with respective fixes.

#### 1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during
	the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functional-
	ity that processes data.
Numeric Errors	Weaknesses in this category are related to improper calcula-
	tion or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like
	authentication, access control, confidentiality, cryptography,
	and privilege management. (Software security is not security
	software.)
Time and State	Weaknesses in this category are related to the improper man-
	agement of time and state in an environment that supports
	simultaneous or near-simultaneous computation by multiple
5 C IV	systems, processes, or threads.
Error Conditions,	Weaknesses in this category include weaknesses that occur if
Return Values,	a function does not generate the correct return/status code,
Status Codes	or if the application does not handle all possible return/status
Describes Management	codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper manage-
Behavioral Issues	ment of system resources.
Denavioral issues	Weaknesses in this category are related to unexpected behaviors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying
Dusilless Logics	problems that commonly allow attackers to manipulate the
	business logic of an application. Errors in business logic can
	be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used
mitialization and Cicanap	for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of
/ inguinents and i diameters	arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written
	expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices
3	that are deemed unsafe and increase the chances that an ex-
	ploitable vulnerability will be present in the application. They
	may not directly introduce a vulnerability, but indicate the
	product has not been carefully developed or maintained.

# 2 | Findings

#### 2.1 Summary

Here is a summary of our findings after analyzing the cBridge Aptos implementations. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings
Critical	0
High	1
Medium	1
Low	3
Informational	0
Total	5

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

#### 2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 high-severity vulnerability, 1 medium-severity vulnerability, and 3 low-severity vulnerabilities.

ID Title Severity Category **Status** PVE-001 High Delay Enforcement Bypass in execute\_-**Business Logic** Fixed delayed transfer() **PVE-002** Low Suggested Consistent Handling Between Coding Practices Fixed Aptos and EVM **PVE-003** Fixed Low Strengthened Owner Authentication in Business Logic peg bridge Module **PVE-004** Medium Confirmed Trust Issue of Admin Keys Security Features **PVE-005** Addition of Delay Period Update in de-Fixed Low **Business Logic** layed transfer Module

Table 2.1: Key Audit Findings

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

## 3 Detailed Results

### 3.1 Delay Enforcement Bypass in execute delayed transfer()

• ID: PVE-001

Severity: High

Likelihood: High

• Impact: Medium

• Target: delayed\_transfer.move

• Category: Business Logic [7]

• CWE subcategory: CWE-837 [3]

#### Description

The cBridge contracts add a much-needed feature for fine-grained risk controls, i.e., the daily transfer volume restriction and the per-transaction transfer volume restriction. While examining the implementation of the delayed\_transfer contract, we notice the intended enforcement of delay period for large transfers may be bypassed.

To elaborate, we show below the code snippet of the related <code>execute\_delayed\_transfer()</code> function. It comes to our attention that the current implementation does not enforce the intended locking period. In other words, both <code>peg\_bridge::execute\_delay\_transfer()</code> and <code>vault::execute\_delay\_transfer()</code> functions can be executed immediately after the <code>mint/withdraw</code> operations.

```
80
        public(friend) fun execute_delayed_transfer(id: vector<u8>): (address, string::
            String, u64) acquires DelayedTransferState {
81
            let state = borrow_global_mut < DelayedTransferState > (@celer);
82
            assert!(table::contains(&state.delay_map, id), DELAYED_TRANSFER_NOT_EXIST);
83
            let v = table::remove(&mut state.delay_map, id);
84
            event::emit_event < DelayedTransferExecutedEvent > (
85
                &mut state.delayed_transfer_executed_event,
86
                DelayedTransferExecutedEvent {
87
88
                    receiver: v.receiver,
89
                    coin_id: v.coin_id,
90
                    amt: v.amt,
91
                },
92
            );
93
            (v.receiver, v.coin_id, v.amt)
```

```
94 }
```

Listing 3.1: delayed\_transfer::execute\_delayed\_transfer()

**Recommendation** Only allows a delayed transfer to be executed if the locking period expires. An example revision is shown as follows. In addition, the affected <code>execute\_delayed\_transfer()</code> function needs to be strengthened to have the <code>friend</code> declaration.

```
public(friend) fun execute_delayed_transfer(id: vector < u8>): (address, string::
80
            String, u64) acquires DelayedTransferState {
81
            let state = borrow_global_mut < DelayedTransferState > (@celer);
82
            assert!(table::contains(&state.delay_map, id), DELAYED_TRANSFER_NOT_EXIST);
83
            let v = table::remove(&mut state.delay_map, id);
84
            assert!(v.blk_ts > timestamp::now_seconds() + state.delay_period,
                DELAYED_TRANSFER_STILL_LOCKED);
85
            event::emit_event < DelayedTransferExecutedEvent > (
86
                &mut state.delayed_transfer_executed_event,
87
                DelayedTransferExecutedEvent {
88
89
                    receiver: v.receiver,
90
                    coin_id: v.coin_id,
91
                    amt: v.amt,
92
                },
93
            );
94
            (v.receiver, v.coin_id, v.amt)
95
```

Listing 3.2: delayed\_transfer::execute\_delayed\_transfer()

Status The issue has been fixed by this commit: 1a1320d.

## 3.2 Suggested Consistent Handling Between Aptos and EVM

• ID: PVE-002

Severity: Low

Likelihood: Low

• Impact: Low

• Target: Multiple contracts

• Category: Coding Practices [6]

• CWE subcategory: CWE-1099 [1]

#### Description

The bridge contract allows to update the signers if the transaction has been signed by the current signers with at least  $\frac{2}{3}$  of the total decision-making powers. While examining the update\_signers() routine, we notice the current implementation is inconsistent with the EVM counterpart(s).

To elaborate, we show below its implementation. Specifically, the variable state.trigger\_time is assigned with the cur\_blk\_time value of the current Aptos block, instead of the blk\_time value in EVM. (line 154).

```
142
         public entry fun update_signers(pbmsg: vector<u8>, sigs: vector<vector<u8>>)
             acquires BridgeState {
143
             let (blk_time, new_signers, total_power) = decode_update_signers_pb(pbmsg);
144
             assert!(total_power > Ou128, INVALID_TOTAL_POWR);
145
             let cur_blk_time = timestamp::now_seconds();
146
             let state = borrow_global_mut < BridgeState > (@celer);
147
             assert!(blk_time <= cur_blk_time + 3600 == true, LESS_THEN_CUR_BLK_TIME);</pre>
148
             assert!(blk_time > state.trigger_time == true, TRIGGER_TIME_TOO_FAR);
149
             let sign_data = state.domain_prefix;
             vector::append(&mut sign_data, b".UpdateSigners");
150
151
             vector::append(&mut sign_data, pbmsg);
             assert!(verify_sig_by_signers(sign_data, sigs, state) == true, VERIFY_SIG_FAIL);
152
153
             state.signers = new_signers;
154
             state.trigger_time = cur_blk_time;
155
             state.total_power = total_power;
156
             event::emit_event<SignersUpdatedEvent>(
157
                 &mut state.signers_updated_events,
158
                 SignersUpdatedEvent {
159
                     signers: new_signers,
                 },
160
161
             );
162
```

Listing 3.3: bridge::update\_signers()

Note this inconsistent handling issue also exists in the peg\_bridge::mint()/burn(), vault::deposit ()/withdraw() functions.

**Recommendation** Use the same handling logic with the EVM blockchain for above mentioned functions.

Status The issue has been fixed by this commit: 0969711.

### 3.3 Strengthened Owner Authentication in peg bridge Module

• ID: PVE-003

• Severity: Low

• Likelihood: Low

• Impact: Low

• Target: peg\_bridge.move

• Category: Business Logic [7]

• CWE subcategory: CWE-841 [4]

#### Description

The peg\_bridge contract provides a public add\_token\_capabilities() function to add burn\_cap, burn\_cap, and burn\_cap capabilities for an account associated with a specified CoinType. Our analysis with this routine shows its current implementation can be improved.

To elaborate, we show below the full implementation of the add\_token\_capabilities() function. Specifically, it should only allow the type\_info::account\_address(&type\_info::type\_of<CoinType>()) address to set various capabilities for a specified CoinType, instead of currently allowing anyone to call this function. The same issue is also applicable to other routines with signer as its arguments, including rm\_token\_capabilities() and add\_token().

```
182
         public entry fun add_token_capabilities < CoinType > (
183
             owner: &signer,
184
             burn_cap: coin::BurnCapability < CoinType > ,
185
             freeze_cap: coin::FreezeCapability<CoinType>,
186
             mint_cap: coin::MintCapability < CoinType >
187
         ) {
188
             let addr = signer::address_of(owner);
189
             assert!(exists < Capabilities < CoinType >> (addr) == false,
                  CAPABILITIES_ALREADY_EXIST);
190
             let coin_cap = Capabilities < CoinType > {
191
                  burn_cap,
192
                  freeze_cap,
193
                  mint_cap,
194
             };
195
             move_to(owner, coin_cap);
196
```

Listing 3.4: peg\_bridge::add\_token\_capabilities()

**Recommendation** Add the necessary owner validation in the above-mentioned add\_token\_capabilities function.

**Status** The issue has been fixed by this commit: 7eab5c5.

#### 3.4 Trust Issue of Admin Keys

• ID: PVE-004

• Severity: Medium

Likelihood: Low

Impact: High

• Target: Multiple contracts

• Category: Security Features [5]

• CWE subcategory: CWE-287 [2]

#### Description

In cBridge Aptos, there is a privileged account, i.e., @celer. This account plays a critical role in governing and regulating the system-wide operations (e.g., add/remove governor, add/remove pauser, reset signers for cBridge, update delay\_period, set epoch\_length, etc.). Our analysis shows that this privileged account needs to be scrutinized. In the following, we use the admin\_manager contract as an example and show the representative functions potentially affected by the privileges of the @celer account.

```
37
        public entry fun add_governor(owner: &signer, governor: address) acquires AdminState
             {
38
            let addr = signer::address_of(owner);
39
            assert!(addr == @celer, NOT_OWNER);
40
            assert!(exists < AdminState > (addr), ADMIN_STATE_NOT_EXIST);
41
            let state = borrow_global_mut < AdminState > (addr);
42
            assert!(table::contains(&state.governors, governor) == false, GOVERNOR_EXIST);
43
            table::add(&mut state.governors, governor, true);
44
45
46
        public entry fun rm_governor(owner: &signer, governor: address) acquires AdminState
47
            let addr = signer::address_of(owner);
            assert!(addr == @celer, NOT_OWNER);
48
49
            assert!(exists < AdminState > (addr), ADMIN_STATE_NOT_EXIST);
50
            let state = borrow_global_mut < AdminState > (addr);
51
            assert!(table::contains(&state.governors, governor), GOVERNOR_NOT_EXIST);
52
            table::remove(&mut state.governors, governor);
53
       }
54
55
        public entry fun add_pauser(owner: &signer, pauser: address) acquires AdminState {
56
            let addr = signer::address_of(owner);
57
            assert!(addr == @celer, NOT_OWNER);
58
            assert!(exists < AdminState > (addr), ADMIN_STATE_NOT_EXIST);
59
            let state = borrow_global_mut < AdminState > (addr);
60
            assert!(table::contains(&state.pausers, pauser) == false, PAUSER_EXIST);
61
            table::add(&mut state.pausers, pauser, true);
62
       }
63
64
        public entry fun rm_pauser(owner: &signer, pauser: address) acquires AdminState {
65
            let addr = signer::address_of(owner);
```

```
assert!(addr == @celer, NOT_OWNER);
assert!(exists < AdminState > (addr), ADMIN_STATE_NOT_EXIST);
let state = borrow_global_mut < AdminState > (addr);
assert!(table::contains(&state.pausers, pauser), PAUSER_NOT_EXIST);
table::remove(&mut state.pausers, pauser);
}
```

Listing 3.5: admin\_manager.move

We understand the need of the privileged functions for proper cBridge Aptos operations, but at the same time the extra power to the @celer may also be a counter-party risk to the cBridge Aptos users. Therefore, we list this concern as an issue here from the audit perspective and highly recommend making these privileges explicit or raising necessary awareness among protocol users.

**Recommendation** Make the list of extra privileges granted to cBridge Aptos explicit to cBridge Aptos users.

**Status** This issue has been confirmed.

## 3.5 Addition of Delay Period Update in delayed\_transfer Module

ID: PVE-005Severity: Low

• Likelihood: Low

Impact: Low

• Target: delayed\_transfer.move

• Category: Business Logic [7]

• CWE subcategory: CWE-841 [4]

#### Description

DeFi protocols typically have a number of system-wide parameters that can be dynamically configured on demand. The Celer cBridge protocol is no exception. Specifically, if we examine the delayed transfer feature, it has defined a number of protocol-wide risk parameters, such as delay\_period and delay\_threshold. In the following, we show the corresponding routines that allow for their changes.

To elaborate, we show below the full implementation of the add\_token() function. Specifically, it allows for the dynamic addition of a new token with customized delay\_threshold and vol\_cap. However, it comes to our attention the setter for the important delay\_period is currently missing.

```
public entry fun add_token < CoinType > (

governor: & signer,

min_burn: u64,

max_burn: u64,

delay_threshold: u64,

vol_cap: u64) acquires PegBridgeState {
```

```
171
             assert!(admin_manager::is_governor(signer::address_of(governor)), NOT_GOVERNOR);
172
             assert!(exists < PegBridgeState > (@celer), STATE_NOT_EXIST);
173
             let state = borrow_global_mut < PegBridgeState > (@celer);
174
             let coin_id = type_info::type_name<CoinType>();
175
             if (table::contains(&state.coin_map, coin_id)) {
176
                 let cur_state = table::borrow_mut(&mut state.coin_map, coin_id);
177
                 cur_state.min_burn = min_burn;
178
                 cur_state.max_burn = max_burn;
179
                 cur_state.delay_threshold = delay_threshold;
180
                 cur_state.vol_cap = vol_cap;
181
             } else {
182
                 table::add(&mut state.coin_map, coin_id, CoinConfig {

```

Listing 3.6: peg\_bridge::add\_token()

These parameters define various aspects of the protocol operation and maintenance and need to exercise extra care when configuring or updating them. Our analysis shows the update logic on the delay\_period parameter needs to be supported.

**Recommendation** Add necessary setters to support dynamic reconfiguration of important protocol-wide parameters.

Status The issue has been fixed by this commit: 1a1320d.

# 4 Conclusion

In this audit, we have analyzed the cBridge Aptos design and implementation. The audited cBridge Aptos is the extension of cBridge in Aptos blockchain, which greatly enriches the Celer Network ecosystem. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
